

Why anjia-home.net breaks on phones

A measured review of the live site across 11 device sizes — what is broken, why it is broken, and what it costs the business.

Subject	anjia-home.net — Anjia Property Management Co., Ltd.
Scope	Public marketing site: home, projects, houses, about, process, news, contact
Measured	4 September 2026, against the live production site
Method	Headless Chrome (v131) driven over the DevTools protocol; real viewport emulation at 11 widths from 320px to 1920px; layout geometry read from the live DOM, not estimated from screenshots
Findings	25 issues — 5 critical, 8 high, 8 medium, 4 low

Rendered page width is a constant 479px on every phone

Anything narrower than 479px scrolls sideways. The gap is what the user cannot see.

The single most consequential finding: the page always renders 479px wide, whatever the phone.

The short version

The desktop site is competent. The phone site is not — and phones are where property buyers browse. Three things are wrong, in descending order of cost:

- **The page is wider than the phone.** Every screen narrower than 480px scrolls sideways. On a 360px Android — the most common width in the world — 119px of every section is off-screen. The cause is one CSS mistake, repeated down one component. We found it and verified the fix.
- **There is no navigation on mobile.** Below 768px the header keeps the logo and drops *Thailand*, *About*, *Process*, *News*, *Contact* and the *Free Consultation* button. No hamburger replaces them. A phone visitor on the homepage has no menu and no call to action.
- **The interface has no design system.** 383 distinct colours, 25 font sizes, 25 corner radii, 85 shadows and 18 breakpoints across one stylesheet. That is why it reads as generic and assembled rather than designed, and why it reflows differently at every screen size.

Underneath those sit an invalid certificate on the bare domain, 1.1 MB of uncompressed JavaScript and CSS, and a site that search engines see as an empty page. The company is buying Google Ads traffic and sending it into this.

What it costs

Symptom	Measured	Business consequence
Sideways scroll below 480px	119px hidden at 360px	Copy and prices are cut off mid-sentence on the majority of Android phones
No mobile menu or CTA	0 of 6 nav items below 768px	A phone visitor cannot reach Projects, About or Contact from the homepage
Floating buttons over content	3 buttons, ~2.5% of screen, fixed	Overlap listing text and testimonial copy on every mobile page
Uncompressed bundles	1.08 MB raw JS + CSS	Roughly 4–5x more data than needed on a mobile connection
Empty HTML for crawlers	0 words server-rendered	Organic search cannot index any listing; all traffic must be paid
Invalid TLS on bare domain	cert names asu-home.com	Typing the domain without "www" can produce a browser security warning

How this was measured

Every number here came from the live site, read out of the browser's own layout engine. Chrome was driven headlessly with true device-metric emulation at each width; the page was then rendered inside an exact-width frame so that reported geometry could not be distorted by the host window. Screenshots and measurements come from the same run, so the pictures and the numbers describe the same page state.

1 — The mobile break

This is the defect that makes the site feel broken on a phone, and it has a single cause.

The same homepage at six widths. Red frames scroll sideways; green does not. The layout only becomes correct at 768px.

What happens

The document is 479px wide at every mobile width we tested. The phone viewport is narrower, so the browser adds horizontal scrolling and the user sees a slice of the page that slides under their thumb. Section headings, prices and body copy run off both edges.

iPhone 14 (390px), same scroll position. Left: page pushed fully left. Right: pushed fully right. The content moves 89px — it should not move at all.

Why it happens

The News & Market Insights section is a CSS Grid. Its two panels are grid items, and a grid item defaults to `min-width: auto`, which means *never shrink below your own content*. Inside each panel, an article row is itself a grid with a max-content date column that refuses to wrap. The refusal cascades: the date will not shrink, so the row will not, so the panel will not — and the panel bursts out of its 324px track to 461px, dragging the whole document to 479px.

The developer already knew about this class of bug — `min-width: 0` and `minmax(0, 1fr)` appear correctly throughout the rest of the stylesheet, including on the parent grid. It was missed on this one chain.

The fix, verified

We injected the following into the live page and re-measured at 320, 360 and 390px:

```
.insights__panel,  
.insights__articles,  
.insightArticle,  
.insightArticle__heading,  
.insightArticle article { min-width: 0 }
```

Viewport	Document width before	After the rule	Result
320px	479px	320px	no overflow
360px	479px	360px	no overflow
390px	479px	390px	no overflow

Five selectors. The entire horizontal-scroll problem disappears at every width. This is worth shipping on its own, today, ahead of any redesign.

2 — Behaviour across screen sizes

Eleven widths, measured on the live homepage. "Overflow" is how far the document extends beyond the screen; "small targets" counts interactive elements below the 44px minimum that Apple and WCAG both specify.

Device	Width	Overflow	Nav items	Small targets	Fixed overlays	Verdict
Small Android / SE1	320	159px	0 of 6	30 of 58	24%	broken
Galaxy S / common Android	360	119px	0 of 6	30 of 58	19%	broken
iPhone SE2 / 8	375	104px	0 of 6	30 of 58	25%	broken
iPhone 14 / 15	390	89px	0 of 6	31 of 58	20%	broken
Pixel 7	412	67px	0 of 6	31 of 58	20%	broken
iPhone 15 Pro Max	430	49px	0 of 6	31 of 58	21%	broken
iPad mini portrait	768	none	6 of 6	32 of 58	18%	usable
iPad Pro landscape	1024	none	6 of 6	32 of 58	13%	usable
Laptop	1280	none	6 of 6	—	9%	good
Desktop	1440	none	6 of 6	—	9%	good
Desktop HD	1920	none	6 of 6	—	9%	good

Read the table top to bottom and the pattern is stark: the site is designed for desktop and degrades until, below 480px, it stops working. There is no width at which the mobile experience is merely compromised — it is either fine or broken.

3 — The missing mobile navigation

Client Testimonials

iPhone 14. The header holds a logo, a currency icon and a language dropdown — nothing else. The three orange buttons sit on top of the testimonial text.

- Below 768px the header renders **only the brand link**. *Thailand, About, Process, News, Contact* and the *Free Consultation* button are all removed by media query.
- Nothing replaces them: we found no hamburger, no drawer, no bottom bar. We checked for the usual markers directly in the DOM and there is no menu toggle of any kind.
- The consequence is blunt: a visitor who lands on the homepage from an ad has no way to reach any other page, and no visible call to action, unless they scroll to the footer.
- The brand wordmark wraps onto two lines at 360px, which is why the logo block looks broken on Android.

4 — Floating buttons that sit on the content

- A fixed rail of three buttons — *AI Service, Contact Us, Follow Us* — is pinned to the right edge at every size. On mobile it overlaps body copy, star ratings and testimonial text, as above.
- The cookie banner takes a further 16% of a 390px screen and covers the first property card until dismissed.
- Together the fixed layers occupy **19–25% of the mobile viewport** before the user has scrolled.

- This is a WeChat mini-program convention. It reads as native inside WeChat and as clutter on the open web — which is consistent with the site being built on a WeChat mini-app backend (see section 7).

5 — Why it looks generic

"Messy" and "not unique" are usually design opinions. Here they are measurable. These are counts from the single stylesheet the site ships:

Property	Distinct values in use	What a designed system uses	Reading
Colours	383	12–24 tokens	No palette. Values were picked per component.
CSS variables	7	40–80	Almost nothing is tokenised, so nothing is reusable.
Font sizes	25 (9px to 46px)	6–8 steps	No type scale — sizes were nudged by hand.
Corner radii	25 (2px to 26px)	3–4 steps	Cards do not share a corner. This is why nothing looks related.
Shadows	85	3–5 elevations	No depth system; every card floats differently.
Breakpoints	18	3–5	Components reflow at different widths — see below.
z-index values	18 (up to 1000)	a named scale	Stacking was resolved by trial and error.

The breakpoint problem, specifically

The stylesheet breaks at 360, 480, 520, 560, 620, 640, **720 and 721**, 760, 860, 880, 900, 960, 1050, 1060, 1080, 1180 and 1320 pixels. Two breakpoints one pixel apart is the signature of per-component patching: each section was fixed in isolation when someone noticed it looked wrong, rather than against a shared grid.

The visible effect is what a viewer describes as "it breaks differently on every phone". At any given width, some components have switched to their narrow layout and others have not, so the page never resolves into one coherent rhythm — the gutters, column counts and card proportions disagree with each other.

5b — The site is a white-label template, and we found its twin

The strongest evidence that the design is not distinctive is not a matter of taste. The site runs on a third-party property platform — the asset bucket, the component names and the build output all carry the vendor name **Nextline** — and other agencies run the same product.

While investigating the certificate problem in 7.1 we found the twin by accident: the bare domain serves a certificate issued to `asu-home.com`. That is a different property company on the same server, running the same platform. Its homepage is below.

Two different companies, unedited screenshots taken minutes apart.

What is identical

- The **positioning line is word for word the same**: "Invest Globally, Unlock the Future: Your Cross-Border Real Estate Expert". This sentence is not Anjia's claim about Anjia — it is the vendor's placeholder, and a competitor is making it too.
- The header: same layout, same native language dropdown, same red *Free Consultation* button in the same corner.
- The cookie notice: identical wording, identical two-button treatment, identical position.
- The navigation, the section order, the card shapes and the floating action rail.

Why this matters more than it looks

A buyer comparing cross-border agencies will open several tabs. If two of them are the same website with different logos, the differentiating claim in the headline is destroyed by the page making it. Worse, the claim being duplicated is precisely the one the business depends on — that this firm, specifically, can be trusted across a

border.

This also reframes every earlier finding. The 383 colours, the 18 breakpoints and the missing mobile menu are not Anjia's design decisions to defend — they are inherited. Anjia cannot fix them inside the template and cannot differentiate inside it either. That is the case for a front-end of their own.

6 — Form controls fall back to the operating system

The site renders **nine native** `<select>` **elements**, all with the browser default appearance: language, property type, price, bedrooms, sort order, purpose, country, city and district.

- On a phone these do not open a styled menu — they hand off to the operating system, which takes over the screen with its own radio list in its own typeface. The brand disappears at the exact moment the user is making a choice.
- They sit directly beside custom-styled controls. In the hero filter bar, *All types*, *Any price*, *Any bedrooms* and *Newest* are native dropdowns while *New projects* is a custom button — four different chevrons and one that has none, in a single row.
- Five of the nine are only 18px tall, well under the 44px minimum touch target.
- The language switcher is the worst placement: it is the first thing an international buyer touches, and it is the least branded element on the page.

7 — Infrastructure and delivery

CRITICAL

7.1. The bare domain presents the wrong certificate

A request to `https://anjia-home.net` is answered with a certificate issued to `asu-home.com`, which does not cover this domain. Strict clients reject the connection outright; browsers show a full-page security warning.

It compounds: `http://anjia-home.net` issues a 301 redirect *into* the broken HTTPS address, so the plain-HTTP entry point leads to the warning rather than around it. Only `www.anjia-home.net` serves a valid certificate.

For a business asking strangers to wire money across a border, a certificate naming a different company is the most expensive kind of first impression. Reissue the certificate with both names on it.

HIGH

7.2. Nothing is compressed

The server sends JavaScript and CSS with no Content-Encoding, even when the browser asks for gzip: 607 KB of application code, 283 KB of libraries and 210 KB of CSS, all raw. Gzip alone would cut roughly 1.08 MB to something near 250 KB.

No Cache-Control header is sent either, so returning visitors re-download everything. Both are nginx one-liners.

HIGH

7.3. Search engines see an empty page

The site is a client-rendered Vue application: the HTML delivered to a crawler contains an empty `<div id="app">` and nothing else. No listing, price, location or article exists in the served markup.

Compounding it: the title is the literal string "anjia-property" on every route including /projects and /houses; there is no meta description, no Open Graph tags and no canonical URL; the homepage has no `<h1>`; and although the site offers English, Thai, Chinese and Japanese, it declares no `hreflang` and hard-codes `lang="zh-CN"` in the shell while serving English.

The site carries a Google Ads conversion tag, so the company is *paying* for the traffic that organic search cannot deliver.

MEDIUM

7.4. The website runs on a WeChat mini-program backend

Every data call goes to `/api/wechat-app/...`, and the homepage alone makes eight separate dictionary requests (property type, listing level, elevator type, landscape, unit, and so on) before it can draw a filter bar.

This explains several surface symptoms at once: the floating action rail, the Chinese-language shell, and error messages that return Chinese text to English-speaking users — a failed request renders `URL ...` regardless of the language selected.

The API also returns HTTP 200 for logical errors, which hides failures from monitoring and caching.

MEDIUM

7.5. No security headers, and the site can be framed

There is no HSTS, Content-Security-Policy, X-Frame-Options or X-Content-Type-Options. Any third party can embed the site in an invisible frame on their own domain — we relied on exactly this to run parts of the audit — which is the setup for clickjacking a contact form.

A Google Maps browser key is embedded in the bundle (AIza...L89Y, redacted). That is normal for Maps, but it is only safe if HTTP-referrer restrictions are set on the key. Worth confirming in the Google Cloud console — an unrestricted key can be used by anyone and billed to you.

8 — Content and imagery

- **8 of 14 homepage images carry no alt text**, and none declare width or height — so the layout jumps as images arrive, and screen readers announce nothing.
- **10 of 14 images are served far larger than the box they are drawn into**, which is a large part of the mobile payload.
- **Ten text elements render below 12px**, with 9px and 10px present in the stylesheet — below the threshold at which most people can comfortably read on a phone.
- **Listing titles are machine-assembled**: "LAGUNA BEACH RESORT 2 24.95 Sq.m. Studio 1 Bathroom" is a database concatenation, not a name. Premium inventory needs written titles.
- **The hero is generic stock imagery** — a rendered skyline that is not any property being sold. The one thing a property agency owns is photographs of real buildings.

Where the listing photographs come from

The filenames on the image bucket are worth a look on their own. Of the 36 listing images we retrieved, the cover photos include files named Screenshot_2569-09-03_at_16.25.37.jpg and several siblings — macOS screenshots, dated in the Thai Buddhist calendar, used directly as property covers. Others carry Facebook's CDN naming (..._10238483822492663_..._n.jpg), meaning they were saved out of Facebook posts. At least one is a 420×300 file whose name contains _wm_ — a watermarked thumbnail from another site.

Two separate problems follow. The quality one is visible to buyers: screenshots of listings are not photographs of buildings, and premium pricing is not credible on them. The other is that images lifted from Facebook posts and watermarked from third-party sites carry someone else's copyright. Worth an inventory before the redesign, because the new layout gives photography far more room than the current one does.

9 — On "premium niche condos"

The site does not currently sell a premium niche, and that is the strategic problem underneath the visual one. Measured from the live listings:

	Measured on the live site
Property types	Condo, Villa, Townhouse, Detached house, Land, Commercial
Price range	1.09M THB to 131M THB — roughly US\$30,000 to US\$3.6M
Locations	Pattaya, Jomtien, Bangkok (Bangna, Bueng Kum, Nawamin)
Positioning line	"Invest Globally, Unlock the Future: Your Cross-Border Real Estate Expert"

A 120-fold price spread is not a niche, and the interface reinforces the confusion by giving a 1.09M THB studio and a 131M THB villa the identical card. A buyer at either end reads the other end as evidence they are in the wrong place.

The genuine differentiator is visible in the site's own copy and is currently buried: this is a **cross-border service business**. It sells Thai property to overseas — largely Chinese — buyers, and then manages the asset for owners who do not live there. The testimonials are explicit about it: *"I am usually away from Pattaya, so the team handles leasing, repairs, and daily management."*

That is a defensible position. A search box on a stock skyline is not — it competes head-on with FazWaz, DDproperty and Hipflat, portals with far larger inventories and budgets. The redesign should lead with the thing those portals cannot do: buying safely in a country you do not live in.

10 — What to fix, in order

Ordered by cost of the problem divided by cost of the fix.

#	Fix	Effort	Why first
1	Add min-width: 0 to the five insights selectors	minutes	Removes horizontal scrolling on every phone below 480px. Verified.
2	Reissue the TLS certificate covering the bare domain	hours	Removes a browser security warning on the address people actually type.
3	Turn on gzip/brotli and cache headers in nginx	hours	Cuts roughly 1.08 MB to about 250 KB. Two config lines.
4	Build a real mobile menu and keep the primary CTA visible	1–2 days	Restores navigation and the conversion path to every phone visitor.
5	Move the floating rail out of the content, or into a single bottom bar	1 day	Stops the buttons covering prices and testimonials.
6	Replace the nine native selects with one styled control	2–3 days	Keeps the brand on screen at the moment of choice; fixes 18px touch targets.
7	Define tokens: colour, type scale, radius, elevation, spacing	3–5 days	The root cause of "generic". Everything downstream gets cheaper.
8	Consolidate 18 breakpoints to 3–4 on one grid	2–3 days	Makes the layout resolve coherently at every width instead of per component.
9	Server-render or pre-render for crawlers; per-page titles, meta, hreflang	3–5 days	Lets organic search carry traffic the ad budget currently buys.
10	Rewrite listing titles; shoot or license real property photography	ongoing	The premium positioning is not credible on stock renders and concatenated strings.
11	Re-position around cross-border service rather than listing search	strategic	Competes where the big portals cannot follow.

Items 1–3 are configuration and cost almost nothing. Items 4–8 are the redesign. Items 9–11 decide whether the site earns traffic or keeps renting it.

Measured 4 September 2026 against the live site. All figures were read from the browser's layout engine at the stated viewport widths and can be reproduced with the capture scripts accompanying this report. Screenshots are unretouched.
